Phenytoin Newborn use only

Alert	High risk medicine. Rapid IV infusion can cause cardiovascular collapse. Phenytoin concentration is	
AICH	reported in mg/L. To convert mg/L (microgram/mL) to micromol/L: Multiply by 3.964.	
Indication	Treatment of neonatal seizures.(1-4)	
Action	Inhibition of neuronal sodium influx, suppression of sodium action-potentials, inhibition of neuronal calcium influx, enhancement of GABA neurotransmission, and blockade of inotropic receptors for glutamic acid.	
Drug type	Hydantoin derivative anticonvulsant	
Trade name	DBL Phenytoin Injection	
	Dilantin Paediatric Suspension	
Presentation	100 mg/2 mL ampoule; 250 mg/5 mL ampoule 30 mg/5 mL oral suspension	
Dose	IV or Oral (1-6)	
	IV Loading dose: 20 mg/kg	
	Maintenance dose: Start 12 hours after loading dose. First 7 days of life:	
	Term infants: 2.5 mg/kg/dose every 12 hours (range 4–8 mg/kg/day)	
	Preterm infants: 2.5 mg/kg/dose every 24 hours. Titrate as per serum concentrations.	
	8–30 days:	
	Term infants: 2.5 mg/kg/dose every 8 hours (range 4–8 mg/kg/day)	
	Preterm infants: 2.5 mg/kg/dose every 12 hours. Titrate as per serum concentrations.	
	Beyond 30 days:	
	Term infants: 2.5 mg/kg/dose every 6 hours	
	Preterm infants: 2.5 mg/kg/dose every 8 hours. Titrate as per serum concentrations.	
	Oral	
	Maintenance : start same as for IV maintenance. Average oral bioavailability 75%. Monitor concentrations and adjust dose accordingly.	
Dose adjustment	Therapeutic hypothermia: Check serum concentration at 24 hours after loading and on day 4 and 7 if	
bose adjustment	therapy continued.(7)	
	ECMO: Larger doses may be needed to achieve comparable serum concentration.(8)	
	Renal impairment: Insufficient information to recommend any specific dose adjustment.	
	Hepatic impairment: Dosage escalation should be gradual.	
Maximum dose		
Total cumulative		
dose Route	IV, Oral	
Preparation	IV: Draw up 2 mL (100 mg of phenytoin) and add 18 mL sodium chloride 0.9% to make final volume of 20 mL with a final concentration of 5 mg/mL. Administer through filter immediately after dilution. Do NOT use if solution becomes cloudy or hazy.	
	Oral: Shake bottle well prior to measuring dose.	
Administration	IV: Infuse over 30 minutes (maximum 1 mg/kg/minute) preferably via a central line or large vein (rare risk of purple glove syndrome with peripheral administration). Flush the line with sodium chloride 0.9% before and after completion of the infusion. IV Maintenance dose can be infused over 5 minutes (maximum 1 mg/kg/minute).	
	Oral: May be given with or without feeds but administration with respect to feeds should be consistent. If possible, give apart from other medications.	
Monitoring	Blood pressure and continuous ECG during stabilisation.	
	Infusion-related reactions: hypotension, bradycardia and arrhythmias during infusion.	
	Continuous cardiorespiratory monitoring, blood pressure, renal function, liver function, blood glucose,	
	full blood count.	
	Long-term therapy: Consider thyroid function tests, calcium, phosphate, 25-hydroxy vitamin D and	
	alkaline phosphatase.	

	Therapeutic Drug Concentration Monitoring: Note phenytoin elimination half-life is variable and steady-
	state may not yet be reached (can take up to 5–10 days) in the initial serum samples.
	Take initial concentration 24 hours after loading dose and then weekly if continued on phenytoin
	therapy. Concentrations need to be monitored more closely in very preterm or extreme low birth weight
	infants.
	Adjust the dose as per serum concentration and seizure control.
	In preterm infants, monitoring needs to be individualised because of long and variable half-life.
	Dosage/dose form changes: Serum concentrations should also be checked after dose adjustments or
	dose form change (e.g. switching from IV to oral) during stabilisation therapy with similar timing as
	above.
	Target Range: Note reference ranges are in total phenytoin concentration; reference ranges are different
	for free phenytoin concentrations. Serum therapeutic range infants ≤ 28 days: 6–15 mg/L (24–60
	micromol/L); infants > 28 days: 1020 mg/L (40–80 micromol/L).
	In severely ill infants and those with hypoalbuminaemia, uremia or concomitant valproic acid, consider
	measuring free phenytoin concentrations. For free phenytoin, target range is 0.5 to 1.4 mg/L (2 to 5.6
	micromol/L). Typical free phenytoin is one-tenth of total phenytoin as phenytoin is 90% protein bound.
	If total concentration is above upper range but below 30 mg/L (120 micromol/L), withhold dose.
	Concentrations above 30 mg/L (120 micromol/L) are considered toxic and infant may display signs of
	overdose and should be monitored especially for cardiovascular symptoms/signs.
	Adjustment of dose according to serum concentration: Phenytoin does not follow linear kinetics so an
	increase in dose may cause a disproportionate increase in serum concentration. If a dose increase is
	required, do so gradually (no more than 10% of the daily dose at any one time) and consult
	pharmacy/neurologist.
Contraindications	Known hypersensitivity to phenytoin, severe sinus bradycardia, and sinoatrial block, second and third
	degree AV block or Stokes - Adams syndrome.
Precautions	If patient is hypotensive prior to starting phenytoin, consult the treating neonatologist. If impaired
	hepatic or renal function, may require decreased dosage. Phenytoin is highly protein bound.
	Concentration of free phenytoin is higher in infants with hypoalbuminaemia and may cause toxicity even
	if the total phenytoin serum concentration is within therapeutic range. Increased free fraction of
	phenytoin can also occur in infants with hyperbilirubinaemia, renal impairment, or uraemia.
	Consider weaning instead of abrupt cessation of the drug (see special comments section).
Drug interactions	Monitor phenytoin concentrations closely if given concurrently with the following medications:
	Erythromycin, trimethoprim/sulfamethoxazole, amphotericin, fluconazole, miconazole, amiodarone,
	omeprazole and ranitidine which may increase phenytoin concentrations. Fluoroquinolones (e.g.
	ciprofloxacin, moxifloxacin), rifampicin, folic acid and calcium may decrease phenytoin concentrations. In
	the case of calcium, administration should be separated by at least 1 hour to reduce the interaction.
	Concurrent administration of phenytoin with phenobarbital (phenobarbitone) has variable effects on
	serum concentrations of either drug. Serum concentrations should be monitored for both drugs. Some
	medications are affected by phenytoin (monitor the concentration of the medication if possible): folic
	acid, thyroxine, vitamin D, calcium, corticosteroids (e.g. dexamethasone), caffeine, frusemide, digoxin
	and vecuronium may have their concentrations reduced. Phenytoin may also lower the blood
	concentrations of methadone, possibly manifesting withdrawal earlier in neonatal abstinence syndrome.
	Other interactions: Diazoxide may reduce the serum concentration of phenytoin and phenytoin may
	increase the hyperglycaemic effects of diazoxide. Dopamine used concurrently with phenytoin may cause
	profound hypotension. Beta-blockers (e.g. propranolol, sotalol) used concurrently with phenytoin may
	cause hypotension and may produce additive cardiac depressant effects.
Adverse reactions	Extravasation causes tissue inflammation and necrosis due to high pH and osmolality. Monitor IV
	insertion site.
	May cause bradycardia, arrhythmias, hypotension during infusion (more common if administration is too
	rapid).
	Cardiac arrhythmias, hypotension, hyperglycaemia, constipation, interstitial nephritis, hepatitis,
	macrocytosis, megaloblastic anaemia (usually responds to folic acid supplementation) and blood
	dyscrasias.
	More likely with long-term use: Gingival hyperplasia, hirsutism, coarsening of facial features, folic acid
	deficiency, vitamin D deficiency, osteomalacia and hypothyroidism (only a few case reports in patients
	taking thyroxine, not in euthyroid patients).

	Rare but potentially fatal skin reaction: Phenytoin is associated with the anticonvulsant hypersensitivity syndrome a variant of Drug Reaction with Eosinophilia and Skin manifestations (DRESS). If DRESS is
	suspected, stop phenytoin immediately. Symptoms include: skin eruptions including Stevens Johnson
	syndrome or toxic epidermal necrolysis, eosinophilia, acute hepatotoxicity; fever; and abnormal lymph
	nodes; facial and/or tongue swelling; hives. There is marked cross-reactivity with other aromatic anti-
	epileptics. The human leukocyte antigen (HLA) allele responsible for this reaction is almost exclusively
	expressed in patients of Asian ancestry including Chinese, Filipino, Malaysian, South Asian Indian, Korean,
	Japanese and Thai.
	Signs of phenytoin overdose: Nystagmus, cardiovascular collapse and/or CNS depression and dyskinesias.
	High serum concentrations are associated with seizures.
Compatibility	Fluids: Sodium chloride 0.9% (for up to 2 hours)(19)
	Y-site: Do not mix with other drugs.
Incompatibility	Fluids: Glucose 5%, glucose 10% (not tested) (15), sodium chloride 0.45% (19)
	Y-site: Amino acid and lipid solutions. Do not mix with other drugs.
Stability	Diluted IV solution should be used as soon as possible. Discard unused portion.
Storage	Store below 25°C. Protect from light.
Excipients	IV: Propylene glycol, ethanol absolute, water for injections, sodium hydroxide, hydrochloric acid
	Oral suspension: sodium benzoate, sucrose, glycerol, aluminium magnesium silicate, carmellose sodium,
	polysorbate 40, vanillin, orange flavour, ethanol, carmoisine, sunset yellow FCF, citric acid monohydrate,
	hydrochloric acid, banana flavour and purified water
Special comments	Elimination half-life 7–42 hours depending on concentration. Half-life is longer in first 7 days of life.
	Tapered dosing may be required in infants with epilepsy.
Evidence	Efficacy
	Initial treatment of neonatal seizures: Phenytoin (free concentration target level 3 mg/L) compared to
	phenobarbital (phenobarbitone) (free concentration target level 25 mg/L) has been reported to have
	similar efficacy in control of electrical seizures (one RCT: LOE II).(1) Phenytoin 20 mg/kg compared to
	phenobarbital (phenobarbitone) 20 mg/kg was reported to be less effective in controlling clinical seizures
	(one RCT, LOE II).(2) Phenytoin was shown to only provide about a 10% to 15% increase in seizure control
	when given following phenobarbital (phenobarbitone) failure.(1) Consider phenytoin for treatment of
	neonatal seizures refractory to a first-line anticonvulsant. (GOR C)
	Maintenance treatment of neonatal seizures: Evidence is insufficient to guide maintenance treatment for
	prevention of seizure recurrence after neonatal seizures. Current recommendations include to wean to
	one maintenance seizure medication prior to discharge; and consider weaning all seizure medication
	prior to discharge if single or rare seizures and if seizure-free for at least 4872 hours and risk of
	recurrence not felt to be unusually high.(3)
	Recommended dosing is phenytoin 1520 mg/kg IV, followed by 410 mg/kg IV, daily in 2 to 3 divided
	doses with close monitoring of plasma phenytoin concentrations. Inject slowly at a rate not exceeding 1
	mg/kg/min. Continuous monitoring of the electrocardiogram and blood pressure is essential.(4) (GOR B)
	mg/kg/min. Continuous monitoring of the electrocardiogram and blood pressure is essential.(4) (GOR B) Side effects: The incidence of side effects is unclear. Reported side effects (12.5%) from a loading dose

Switching from enteral to intravenous routes may require a dosage adjustment (enteral bioavailability 0.76, 95% CI 0.44 to 1.07), although similar serum concentrations have been reported in preterm infants irrespective of route.(10,11) (LOE IV, GOR C)
	Side effects: The incidence of side effects is unclear. Reported side effects (12.5%) from a loading dose included respiratory depression, bradycardia, oxygen desaturation, drowsiness, vomiting, pyrexia, twitching and hypotension.(5) Reported side effects from maintenance treatment (all age groups) include gastrointestinal side effects (abdominal pain, nausea and vomiting); drowsiness/tiredness/fatigue/sedation; rash; decreased libido or impotence; motor disturbance (including ataxia, incoordination, nystagmus, tremor); dysmorphic and idiosyncratic side effects (gum hypertrophy, hirsutism, acne, other skin problems) and cognitive side effects and impairments, including slowing of mental function, inattention, psychomotor retardation, depression and memory problems.(6) Pharmacokinetics : In children, phenytoin loading dose 20 mg/kg may result in supratherapeutic concentrations.(5) (LOE IV) During the first week after birth, plasma half-life is so variable that no fixed dosage regimen can be derived. Beyond the second week, 8 mg/kg/24 hours is probably inadequate for most infants.(9) (LOE IV) In preterm infants the t½ was much longer (75.4 \pm 64.5 h) and more variable.(9) (LOE IV) Postnatal age independently influenced clearance. Switching from enteral to intravenous routes may require a dosage adjustment (enteral bioavailability 0.76, 95% CI 0.44 to 1.07), although similar serum

compared to non-ECMO neonates (20 vs 11mg/kg/day; p=0.04) with comparable drug levels (8.4 vs 7.4 mg/L; p=0.56).(8)	
Monitoring: Therapeutic target for total phenytoin is 10 to 20 mg/L (40 to 80 micromol/L) and for free phenytoin 0.5 to 1.4 mg/L (2 to 5.6 micromol/L).(12) (LOE IV, GOR C). Total phenytoin concentrations are unreliable for directing therapy in critically ill children. Free phenytoin concentrations should be routinely measured in critically ill children to prevent possible intoxications and ensure therapeutic dosing.(13)	
When free phenytoin concentrations cannot be routinely measured, use total phenytoin concentration with a derivative of the Sheiner-Tozer equation:	
Ctotaladjusted = [Ctotalmeasured x $10.2 - 0.24$ x (ALB - 42) + 0.067 x (UREA - 7)+ 2.53 x VALP] ÷ 10.2 . ¹³⁻¹⁴	
Note, however, that the Sheiner-Tozer equation and all its derivatives are regarded, in general, as biased and imprecise.(14)	
In children with hypoalbuminaemia, uraemia or concomitant valproic acid use, ensure close treatmonitoring and consider a dose reduction of phenytoin a priori.(13) (LOE IV, GOR C)	
To convert from mg/L (microgram/mL) the factor is 3.964. Simply multiply the mg/L value to obtain value in micromol/L.	
Hypothermia can significantly reduce clearance of phenytoin compared with normothermic patients and during and after rewarming phase. There is limited data about saturable metabolism and modelled using Michaelis-Menten Kinetics in neonates. It is advisable to closely monitor the concentration of phenytoin	
in neonates during therapeutic cooling and rewarming phase.(7)
