## Heparin Newborn use only

Alert	High risk medication in A P	INCH Medicines list	under New South Wa	ales Clinical Excellence Commission	
Act	High risk medication in A PINCH Medicines list under New South Wales Clinical Excellence Commission. Also known as unfractionated heparin (UFH). Not equivalent to low molecular weight heparin (LMWH).				
	Use in consultation with ha		•		
	Many concentrations of he	-			
	concentrations are kept in	the unit.			
	In neonatal settings: recor	In neonatal settings: recommend to store the following preparations only: heparinised saline 50 units/5			
	mL and heparin sodium inje				
				ates as it contains benzyl alcohol.	
	However, DBL Heparin sod			ain benzyl alcohol.	
Indication		Primary or secondary antithrombotic prophylaxis. Maintenance of arterial and central venous catheter patency.			
Action			· · ·	by at least 1000-fold. ATIII	
	-	Heparin binds to antithrombin III (ATIII), potentiating ATIII's activity by at least 1000-fold. ATIII predominantly inactivates factor Xa and thrombin (other proteases/clotting factors to lesser degree),			
				ses anti-complementary activity,	
	inhibiting both the classic a	and alternative path	ways.		
)rug type	Anticoagulant				
rade name	Heparin Sodium Injection (	Pfizer), DBL Heparin	Sodium Injection BP		
	Heparinised Saline Injection	n (Pfizer)	-		
resentation	Antithrombotic prophylax				
			oule: 5000 units/5 mL		
	-	•	oule: 1000 units/1 m		
			be used in neonates	s as it contains benzyl alcohol.	
	Maintenance of catheter p	-			
			: 50 units/5 mL (10 un Honorin (1 unit/mL) in	-	
	Also available as premixed infusions (Heparin (1 unit/mL) in sodium chloride 0.9% in 50 mL				
	syringe)				
Dose	syringe)	is <sup>1,2,3</sup>

	DBL vial: Benzyl alcohol. Do not give products that contain benzyl alcohol to neonates.				
	Heparinised saline: Hydrochloric acid, sodium	-			
Special comments	Protamine sulfate is the reversal agent to corr	ect the anticoagulant effect of heparin.			
Evidence	Efficacy				
	Systemic antithrombotic therapy/prophylaxi	<u>s</u>			
	Arterial thrombosis: Spontaneous arterial thrombosis is rare in neonates and the evidence around its				
	management using heparin is limited to case reports only. De Godoy et al reported complete				
	disappearance of an aortic thrombus and clinical improvement in a neonate following 15 days				
	anticoagulation with heparin. <sup>11</sup> Similarly, anticoagulation with heparin following initial thrombolysis of a				
	major aortic thrombus is found to be helpful in improving clinical outcomes of neonates. <sup>12</sup>				
	<u>Venous thrombosis</u> : In a cohort of 53 neonates who received heparin, Moharir et al found significant reduction in propagation of cerebral sino-venous thrombosis (2 vs 30%; P < 0.001). However, no difference				
	was noted in thrombus recanalisation, mortality and long-term disability. <sup>13</sup> Non-life threatening bleeding				
	was seen in 5-6% of neonates.				
	thrombosis with or without inferior vena cava	onates who received heparin therapy for renal vein involvement, there was no difference in irreversible renal y up. <sup>14, 15</sup> In a cohort of 128 neonates with portal vein			
	annage and renaratiopity at long term lollow				

	thrombosis the incidence of lobar atrophy of liver and risk of portal hypertension was not altered by the use of anticoagulants. <sup>16</sup>
	No clinical outcome studies have determined the therapeutic range for heparin in neonates and the APTT therapeutic range and monitoring is extrapolated from adults. One prospective cohort study used a weight-based nomogram to address dosing of heparin in paediatric patients required to achieve adult therapeutic APTT values. Bolus doses of 75 to 100 units/kg resulted in therapeutic APTT values in 90% of children at 4-6 hours after bolus. <sup>17</sup>
	Maintenance of patency of central vascular catheters <sup>1,2, 5-7</sup> Low dose heparin administered as a continuous infusion or regular flushes significantly increases the duration of peripheral catheter patency and reduces the episodes of infusion failure. <sup>5,6</sup> A systematic review involving 267 neonates reported significant reduction in occlusion of peripherally placed percutaneous central venous catheters and higher rates of completion of therapy if heparin is infused at a dose of 0.5unit/kg/hr. <sup>7</sup> Administration of heparin in low doses does not significantly alter the risk of sepsis or intraventricular haemorrhage. <sup>1,5-7</sup> However, Lesko et. al. reported a 4-fold, but statistically not significant, increase in IVH in low-birthweight infants in a case control study (OR, 3.9; 95% Cl, 1.4-11.0). <sup>10</sup> Maintenance of patency of peripheral arterial catheters Heparin is shown to significantly reduce clot formation and maintain patency of peripheral arterial catheter for a longer period. <sup>18</sup> Compared with 1 unit/mL, heparin concentration of 5 units/mL is more
	effective in keeping arterial catheters patent for longer time. <sup>19</sup> Studies found heparinised normal saline superior to heparinised glucose solution, and continuous infusion of heparin in normal saline better compared to intermittent flushing to improve arterial catheter patency. <sup>20,21</sup>
	ANMF consensus on the strength and infusion rate of heparinised IV fluid for catheter patency is a simplified pragmatic recommendation from the evidence.
	<ul> <li><u>Heparin Lock for Central Venous Access Device (CVAD)</u></li> <li>The 'lock' is the intraluminal injection of a limited volume of fluid, after the catheter flush, in the intervals of time when the catheter is not in use, with the purpose of preventing lumen occlusion and/or bacterial colonization. The most appropriate lock solution for central venous access devices is still to be defined.</li> <li>The data available from the literature are still not conclusive and no recommendation is offered by most guidelines.<sup>25</sup> The recommended regimen suggested by the ANMF group is reflective of the current practice in neonatal units.</li> <li>Safety</li> </ul>
	Major bleeding has been reported in children treated for deep vein thrombosis/pulmonary embolism. There are case reports of osteoporosis. Given the adverse effects, and the availability of alternative anticoagulants, long term use of heparin can be avoided. Heparin-induced thrombocytopenia (HIT) has been reported in neonates. Following exposure to heparin for at least 5 days, Schmugge et al reported antibodies against HPF4 in 2.3% children who developed thrombocytopenia and thrombosis. <sup>23</sup> In a systematic review, Avila et. al. reported seroconversion for anti-PF4/H antibodies in 0-1.7% neonates but no neonate fulfilled the combined clinical and laboratory criteria used for the diagnosis of HIT. <sup>24</sup> <b>Pharmacokinetics</b> Studies of heparin in newborns are limited but show that the clearance is faster than for older children because of a larger volume of distribution. It is metabolised by liver and excreted renally within 6 hours
	but may be delayed. Half-life is dose-dependent but averages 1 to 3 hours. Efficacy in neonates may be low due to low antithrombin plasma concentrations. <sup>1</sup>
Practice points	<b>General</b> There are no data from randomised controlled trials to recommend or refute the use of heparin for treatment of neonatal thrombosis. <sup>2</sup> <b>Dose</b> <u>Antithrombotic prophylaxis</u>
	Loading doses and maintenance doses have been adapted from the American College of Chest Physicians Evidence-Based Clinical Practice Guidelines 2012, <sup>1</sup> which were based on paediatric data from a prospective cohort study. <sup>22</sup> (LOE IV GOR D) Loading dose is safer to be infused over 30 minutes in neonates. (ANMF haematology expert group
	opinion) Initial maintenance dose is easier to be administered at 30 units/kg/hr, rather than 28 units/kg/hr. (ANMF haematology expert group opinion) <u>Central vascular catheters</u>

	Heparin infusions at 0.5 units/kg per hour are recommended to maintain CVAD patency. <sup>1,7</sup> (LOE I, GOR B) <u>Peripheral arterial catheters</u>
	Heparin infusions at 0.5 units/mL at 1 mL/hour are recommended. <sup>1</sup> (LOE II, GOR B)
	ANMF consensus on the strength and infusion rate of heparinised IV fluid for catheter patency is a
	simplified pragmatic recommendation from the evidence.
	Heparin Lock for Central Venous Access Device (CVAD)
	The recommended regimen suggested by the ANMF group is reflective of the current practice in neonatal
	units.
	Dose adjustment
	Anti-Xa therapeutic range: While O'Meara study suggests $0.4 - 0.8$ unit/mL, range of $0.3 - 0.7$ unit/mL is adequate for most indications, and most commonly used. Table 1 is a modified regimen of O'Meara study, <sup>3</sup> which was performed in ECMO patients where very tight anticoagulation is required, managed by staff very experience in managing anticoagulation for ECMO circuits; hence, the repeat boluses were
	recommended by O'Meara et. al. when anti-Xa was below the target range. Repeat boluses are not
	required in the majority of non-ECMO patients. Regarding dose adjustment for anti-Xa > 1, advice from the haematologist should be sought as the anti-Xa can be very high and simply reducing the infusion rate may not be appropriate. <sup>3</sup> (ANMF haematology expert group opinion)
	The frequency of testing at 2 hourly intervals is the practice in ECMO circuits but not indicated for routine
	anti-coagulation for non-ECMO patients. Testing too early & too frequently, lends to inappropriate dose
	adjustments. Testing 6 hours after starting infusion and dose changes is adequate as a general guide, and to check with the haematologist on further monitoring. (ANMF haematology expert group opinion) Dose adjustments using APTT monitoring have been adapted from the American College of Chest Physicians Evidence-Based Clinical Practice Guidelines 2012, <sup>1</sup> which were based on paediatric data from a
	prospective cohort study. <sup>22</sup> (LOE IV GOR D)
	For consistency, using APTT monitoring, testing 6 hours after starting infusion and dose changes is
	suggested as a general guide, and to check with the haematologist. (ANMF haematology expert group
	opinion)
